

A Synthetic Note on Reproducible LaTeX Revision

LazyingArt project-owned sample

2 September 2026

Abstract

This synthetic document tests a small, reproducible LaTeX revision. It treats the editor-readable redline as a third build, not as an incidental view of the clean manuscript. It contains no customer material and makes no scientific claim.

1 Method

A manuscript revision should freeze complete old and revised source trees and build each one independently. ~~The checked comparison~~ It should then generate the redline from those exact snapshots. The checked revision state is represented by

$$R = (S_{\text{old}}, S_{\text{new}}, \textcolor{blue}{D}), \quad (1)$$

where the two S terms are named source snapshots and D is the generated diff source. Each source is compiled with the same engine and dependency set.

Table 1: Artifacts checked in the revision workflow.

Artifact	Check
Baseline	Builds <u>independently</u>
Revision	Builds <u>independently</u>
<u>Redline</u>	<u>Builds from the accepted snapshots</u>

2 Verification

The final review checks the clean revised PDF for locations and the redline PDF for visible changes. Build commands, source hashes, tool versions, warnings, and unresolved issues remain in the accompanying manifest.

3 Conclusion

A successful clean build is necessary but not sufficient. The two source snapshots in (1) remain separate and independently buildable. The three-part state keeps both accepted source trees and their generated redline connected without silently overwriting either source.
